APPLICATION FOR LETTERS PATENT

**Resource Classification and Prioritization System**

**Inventors:**

Brian R. Tunning

Jennifer R. Wise

**EV251221797**

**ATTORNEY'S DOCKET NO. MS1-1482US**

## TECHNICAL FIELD

The subject matter relates generally to information systems and more specifically to a resource classification and prioritization system.

## BACKGROUND

Content management systems can help users and administrators to classify data so that intelligible and relevant information may be returned to a specific type of user. For example, a worldwide email system might be able to access resources from many different countries and in many different languages. A user, however, may not need different language versions of the same content or versions of the same content adapted for different cultures. By localizing the content for a particular user or type of user, it is possible to greatly reduce the universe of information to be presented to the user. Localizing content for a user may be thought of either as either gathering desirable information elements together from an undesirably large universe of information, or conversely, filtering out undesirable information elements from a pre-existing set of desirable information elements.

**Fig. 1** shows a conventional manner of localizing resources for a user or application. Within an information universe 100, a common attribute is applied in a filtering process to localize a target environment for a user that is made up of a localized subset 102 of information resources that have the common attribute. A user query 104, for example, can then operate within those information resources in the localized subset 102 that comprise the user's environment.

1 In the context of an application that has access to information resources on  
2 a worldwide scale, one attribute for creating a localized subset 102 of information  
3 resources is language. Another attribute for creating a localized subset 102 of  
4 information resources is the associated country or geopolitical setting of a user or  
5 a resource. These two attributes, language and country, are conventionally used  
6 for localizing information resources, but provide only a rough localization, even  
7 when combined.

8 **Fig. 2** shows a conventional database 200 for arranging attributes used to  
9 localize information resources. The conventional database 200 is typically  
10 represented by a table having a first attribute column 202 and a second attribute  
11 column 204. The first attribute column 202 is typically reserved for the localizing  
12 attribute, "language" 206. Fields for "language" values, such as English 210 and  
13 Spanish 212 are provided. The second attribute column 204 is typically reserved  
14 for the localizing attribute, "country" 208. Fields for "country" values, such as  
15 Canada 214 and Mexico 216 are provided. In a typical conventional content  
16 management system, the conventional database 200 has capacity for only the two  
17 attributes, and applications using the conventional database 200 are often  
18 dependent on this conventional database structure.

19 As shown in **Fig. 3**, a localization of resources by adding a language  
20 attribute value, such as "Spanish" 212, to a country attribute value, such as Mexico  
21 216 results in a localization to only those "Spanish" and "Mexico" resources 302  
22 in the intersection of sets wherein a resource has both an attribute of "Spanish"  
23 212 and an attribute of "Mexico" 216. Such a localization is an improvement over  
24 the non-localized entire universe of information resources 100, but is still not very  
25 specific.

Returning to Fig. 2, to add a third, new attribute 218 for further localizing resources beyond "Spanish" 212 and "Mexico" 216 attributes would require changing the structure of the conventional database 200 to add a third attribute column 220 reserved for the new attribute 218 and new fields for the new attribute values 222, 224. Not only is this difficult to implement if applications are dependent on the structure of the conventional database 200, but the structure of the conventional database 200 would have to be changed every time an attribute is added or subtracted from the structure. Further, using multiple attributes is conventionally avoided because numerous attributes increase the chance for an inaccurate localization as some attributes of lesser importance may be overrepresented compared to others that should be primary determinants of localization results.

## SUMMARY

Subject matter includes an extensible information system, such as an exemplary content management system, and related methods for classifying, prioritizing, and localizing resources and associated content elements. The subject matter allows content to be described, classified, prioritized, and localized with increased flexibility and extensibility over conventional techniques without having to change a data structure of an exemplary content management system hosting the subject matter.

## BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a graphic representation of a conventional method of localizing information.

1 Fig. 2 is a graphic representation of a conventional attribute table for  
2 localizing information.

3 Fig. 3 is a graphic representation of a conventional method of localizing  
4 information using two attributes.

5 Fig. 4 is a graphic representation of an exemplary attribute table according  
6 to one aspect of the subject matter.

7 Fig. 5 is a graphic representation of an exemplary universe of values for the  
8 attributes in the exemplary attribute table of Fig. 4, according to one aspect of the  
9 subject matter.

10 Fig. 6 is a graphic representation of an exemplary method of localizing  
11 information using more than two attributes, according to one aspect of the subject  
12 matter.

13 Fig. 7 is a graphic representation of exemplary localization target criteria.

## DETAILED DESCRIPTION

The disclosed subject matter provides an extensible information system, such as an exemplary content management system, and related methods for classifying, prioritizing, and localizing resources and associated content elements. The subject matter allows content to be described, classified, prioritized, and localized with increased flexibility and extensibility over conventional techniques without having to change a data structure of an exemplary content management system hosting the subject matter.

In one implementation, the subject matter uses an exemplary database structure for classifying attributes and values applicable to resources and their content elements. A first table defines attributes and priorities for a resource or a content element and a second table defines values for the attributes. A third table brings attributes and attribute values together to form sets of localization target criteria. Because values are stored in an extensible part of the database structure—such as a dynamic number of row entries in a table, rather than in a fixed part of the database structure, such as fixed columns representative of a fixed record or field—classification, prioritization, and localization can occur against a variable number of attributes without prior knowledge of the specific fields in a particular table. Using priorities, an exemplary system can intelligently return content elements information that are localized to the characteristics and needs of a particular user. Additionally, users can easily add new attributes using an implementation of the subject matter without writing new code or changing the database structure of an exemplary system.

1       The content elements returned to a user by an exemplary system can be  
2 information in a variety of forms, such as stored data, data packets, search results,  
3 web content, inventory items, etc., that can be classified according to inherent or  
4 assigned attributes. The content elements in an example resource, such as a link to  
5 a magazine article may have content elements each representing a version of the  
6 magazine article, e.g., one version for adults, one for children, one in English, one  
7 in French, and various combinations thereof. Data structures will be described  
8 herein that allow quick, flexible, accurate, and extensible classification,  
9 prioritization, and localization of such content elements.

10       Localization as used herein refers to a process wherein a subset of the  
11 above-mentioned content elements in a system is selected, partitioned, filtered,  
12 directed, and/or marked for a particular population of users, market, and/or a  
13 particular need. Thus, a localization target (herein "target") is a population or  
14 users or a particular need to which localized resources and/or content elements are  
15 directed. A localization of resources or content elements is effected according to a  
16 set of localization criteria (herein "target criteria" or "target criteria set"), usually  
17 composed of one or more attribute values that describe the target population or  
18 need. *The resources and/or content elements to be localized are imbued with*  
19 *attribute values that describe a target.* Hence, a target criterion composed of a  
20 language attribute value of "Japanese" localizes content elements having the  
21 "Japanese" attribute value and also describes the target (the population of users to  
22 which content will be directed), that is, localization criteria are attribute values that  
23 describe the target and the resources directed to the target. A set of localized  
24 content elements and/or the resources that include the content elements is also  
25 sometimes referred to as an "environment." To summarize, localization creates a

1 subset of content elements directed to a target (a population of users or a particular  
2 need) according to target criteria, which are attribute values describing the target.

3 A resource can be thought of as a logical unit of content or a means for  
4 obtaining content, but not the content itself, for example, a text string space in a  
5 certain memory location, a header position in a webpage, a paragraph, a link, an  
6 image, an image with a link, an error string, etc. A resource may exist and be  
7 localized for a particular user or purpose even if the resource does not include  
8 content elements. An instance is a specific content element that exists in a  
9 resource.

10 An exemplary content management system described herein provides for  
11 localization according to a potentially unlimited number of attributes for resources  
12 and/or content elements. The number of attributes that can be selected as a set of  
13 localization criteria is dynamic and, as mentioned, can be changed without altering  
14 the data structure of an exemplary system hosting the subject matter.

15 Further, each attribute selected for localizing content in the exemplary  
16 system can be assigned a weight ("priority") so that important attributes are  
17 influential in achieving a given localization and attributes of lesser significance do  
18 not unintentionally skew localization results.

19 The instant subject matter may be applied to many localization techniques.  
20 In some systems, localization may be implemented by considering each resource  
21 and/or content element in a system and marking those content elements that are to  
22 be members of a localization subset (e.g., storing a marker with the content  
23 element). In another technique, localization may be implemented by marking  
24 resources and/or content elements in a system as potential members of potential  
25 localizations. This may be accomplished, for example, by storing with each

1 resource and/or content element an identification number of a preferred associated  
2 set of localization target criteria, e.g., those attributes and/or attribute values to be  
3 used in a localization that particularly apply to the specific content element. In  
4 other systems, localization may be implemented “on the fly” by considering  
5 resources and content elements in real time and filtering out resources and/or  
6 content elements that do not fit the localization target criteria (do not have an  
7 attribute value designated in the localization criteria). In yet other systems,  
8 localization may be implemented by sequestering or physically storing content  
9 elements in a special space, for example, by writing elected content elements to a  
10 designated directory on a hard drive, etc.

11 The instant subject matter can be implemented by an exemplary mapping  
12 technique, which can be represented by a series of relationships between data  
13 tables. These will now be described.

14 **Fig. 4** shows an exemplary attribute table 400 for an exemplary content  
15 management system. Instead of each attribute constituting an essential column of  
16 a database structure, as in the conventional database 200, wherein a change in the  
17 number of attributes requires a change of database structure, in an exemplary  
18 attribute table 400 there is only one attribute column 402. Various attributes may  
19 be added (without limit) and deleted from the exemplary attribute table 400  
20 without requiring a change in database structure. Instead of relating attribute  
21 values to each attribute in an exemplary attribute table 400, each attribute is  
22 related to a user-selectable priority 404, which may be used for weighting  
23 purposes during a localization 406. A localization according to attributes in the  
24 exemplary attribute table 400 can be executed with greater specificity than with a  
25 conventional database 200, because more attributes can be enlisted for localization

1 406 and each attribute can exert a weighted influence on the localization according  
2 to its priority 404.

3 **Fig. 5** shows an exemplary values table 500 for the exemplary attributes  
4 table 400. In one implementation, the exemplary values table 500 encompasses a  
5 universe of values within a given content management system, that is, the  
6 exemplary values table 500 includes every value in use for every attribute in a  
7 particular content management system. The exemplary values table 500 does not  
8 usually include every possible value of an attribute, the term “universe” of values  
9 means a complete assortment of selected values “in use” in an exemplary system.

10 Part of the ability of an exemplary content management system to expand  
11 without changing its structure is that there is a place for all attributes in same  
12 exemplary values table 500. Rather than having one table for each attribute, e.g.,  
13 one table for all possible colors, one table for all possible languages, etc., to make  
14 attributes useful, the instant subject matter provides a single exemplary values  
15 table 500. In a typical implementation, the exemplary values table 500 does not  
16 get unmanageably large. For example, a hypothetical email implementation of the  
17 subject matter might use an exemplary values table 500 that has approximately  
18 250 rows to localize content according to attributes such as country, language, and  
19 perhaps one or two additional attributes.

20 In some implementations, a value is not placed in the exemplary values  
21 table 500 unless a resource includes an actual instance of a content element that  
22 possesses both the value and its associated attribute. Such implementations of the  
23 subject matter result in a content management system in which operates within  
24 localized content are reliable as to which resources and/or content elements exist  
25 and which do not. In other words, in such an implementation a user who obtains a

1 result knows the result exists, and a user who does not obtain a certain result  
2 knows that the certain result does not exist in the system. Thus, an exemplary  
3 content management system is superior in its ability to indicate existence of  
4 particular content over many types of information search engines that only suggest  
5 a hypothetical fit between search criteria and results found, or suggest a degree of  
6 correlation between search criteria and items on a hit list.

7 In an exemplary values table 500, an attribute 402 such as "language" may  
8 have a dynamic number of associated values 502, such as English, Spanish, Dutch,  
9 etc., and the relationship between an attribute 402 and its associated values 502  
10 may be implemented by storing each value 502 with a pointer to its associated  
11 attribute 402, or storing the value 502 and an associated attribute 402 in pairs, etc.  
12 Hence, a value 502 may be looked up to find its associated attribute 402, and in an  
13 exemplary attribute table 400, the attribute obtained may be looked up to find its  
14 associated priority 404. Each attribute 402 in a dynamic and open-ended list of  
15 attributes 402, may each have a dynamic and open-ended list of values, that is, the  
16 list of values 502 may include a number of values for each of multiple attributes  
17 402. In one extreme case, all the values 502 may have the same associated  
18 attribute 402, while in an opposite extreme case each value 502 may have a  
19 different associated attribute 402. As mentioned, if each value is placed in the  
20 exemplary values table 500 only when a value 502 is associated with an actual  
21 resource or an actual instance of content having the value, then the exemplary  
22 value table 500 becomes a full and complete universe of values in an exemplary  
23 content management system, in which the existence or nonexistence of a particular  
24 content element having a particular value 502 for an attribute 402 can be directly  
25 ascertained. More importantly, when numerous attributes 402 having respective

1 priorities 404 are used in an exemplary content management system, the existence  
2 or nonexistence of a particular content element having a finely tuned mixture of  
3 values 502 for the attributes can be directly ascertained. For a user, this means  
4 that a communication tool, such as email, can be much faster and more efficient as  
5 the raw number of resources it must deal with (i.e., its environment) has been fine-  
6 tuned and greatly minimized a priori through very specific localization. It also  
7 means that the resources can be reliably accessed in implementations wherein  
8 resources are localized only if they exist. A user can reliably conclude that an  
9 unfound resource does not exist in the present localization. This may save a user  
10 the effort of reconfiguring searches and trying to second-guess search criteria.

11 **Fig. 6** shows an exemplary localization 600 according to one aspect of the  
12 subject matter, wherein three attributes 402 are used in localizing content. A  
13 language attribute having a value of "Dutch," a country attribute having a value of  
14 "Belgium," and an age range attribute having a value of "25-30 year olds" are  
15 intersected to localize those resources and/or content elements in an exemplary  
16 content management system having the respective attributes and values. Using the  
17 subject matter, a much smaller subset of content elements is localized than could  
18 be obtained by just using two attributes in a conventional system. Since any  
19 number of attributes may be used in an exemplary content management system, a  
20 very specific localization may be obtained, without altering the data structure of an  
21 exemplary content management system.

22 **Fig. 7** shows an exemplary set of localization target criteria 700 (also  
23 referred to herein as "target"), which are attribute values to be used to perform a  
24 localization. In an exemplary content management system, an exemplary set of  
25 localized target criteria 700 include one or more localization attributes, such as

1 language, country, age range, etc., each having a value used as a criterion for the  
2 localization. Each value in an exemplary set of localized target criteria 700 is  
3 related to an attribute in an exemplary values table 500, which in turn is related to  
4 a priority for the attribute 402 in an exemplary attribute table 400. For example,  
5 within an exemplary target 700, "Dutch" may be a value for a language attribute  
6 assigned a priority of one, "Belgium" may be a value for a language attribute  
7 assigned a priority of two, and "25-30 year olds" may be a value for an age range  
8 attribute assigned a priority of three. When the priorities 404 are added together,  
9 the overall priority sum 702 for the exemplary target 700 adds up to six. To  
10 reiterate, the weight assigned to a given priority may be user-selectable. Actual  
11 priority sum results also depend on a particular weighting method used to rank  
12 attribute priorities. Depending on how the priorities 404 are assigned to the  
13 attributes 402 in the attribute table 400 and the weighting method employed, a  
14 higher priority sum 702 may indicate a more localized target environment 700 as  
15 more attributes and/or narrower attributes are considered in refining the  
16 localization, that is to say, a very specific attribute may result in a very high  
17 priority sum. However, since different weighting methods may be used to assign  
18 numbers to attribute priorities, in some implementations a lower priority sum may  
19 indicate a more specific localization.

20 Exemplary targets (that is, sets of localization target criteria, such as  
21 exemplary target 700) provide a flexible way of retrieving information in a data  
22 system. For example content elements may be ranked from more general to more  
23 specific as a function of how many attributes a particular content element has  
24 associated with it. A user can search for those content elements described by a  
25 certain attribute, such as "language." Or, a user can search for elements described

1 (for instance) by at least four attributes. Similarly, a user could search for content  
2 elements described by attributes whose priority values add up to twelve. The  
3 subject matter allows for easy extensibility, and re-prioritization of attributes  
4 without changes to the structure of an exemplary content management system.  
5 Users can easily add new attributes and change their priority as desired.

6 It should be noted that in some implementations, the various values,  
7 attributes, and priorities in the exemplary tables (e.g., 400, 500) and target criteria  
8 sets (e.g., 700) can be mapped to each other using identification labels, instead of  
9 words from a human language such as English as illustrated. For instance,  
10 integers may be used as the identification labels: localization target criteria set "3"  
11 might contain value "2" for attribute "7," which has a priority of "4."

12 Also, in some implementations, a target criteria set (e.g., 700) is allowed by  
13 the exemplary system logic of the implementation to include only one value of  
14 each attribute (or of certain attributes) in a given target criteria set 700. Such an  
15 implementation would forbid, for example, a target criteria set 700 that includes a  
16 French value and an English value together. This is because a specific content  
17 element, such as a news clipping, is either written in English or French, but not  
18 both at the same time.

19 **Fig. 8** shows an exemplary content management system 800 in which  
20 various pre-established or possible localizations have been performed according to  
21 assorted targets 700, 802, 804, 806, 808, each target having one or more  
22 localization attributes. When a localization is requested by a user or administrator,  
23 the exemplary content management system 800 may compare the priority sum 702  
24 of the subject exemplary target being requested with the priority sums of the pre-  
25 existing or possible target environments 700, 802, 804, 806, 808 to see if any

1 match or are close to the requested localization target. Thus, in some  
2 implementations an exemplary content management system 800 does not need to  
3 perform a localization from scratch when presented with a localization request, but  
4 might derive a localization from pre-existing "stock" localizations.

5 When presented with a localization request, for example, a request for a  
6 target environment that includes the attributes "Dutch," "Belgium," and "25-30  
7 year olds," (attributes that may already exist in a pre-existing target, in this case  
8 the first target 700, for the sake of illustration) an exemplary content management  
9 system 800 may measure the closeness or alternatively the "distance" between the  
10 requested target localization and pre-established target environments 700, 802,  
11 804, 806, 808 (for example, by subtracting the two). The requested target, which  
12 in this example is identical to the first target 700, has a priority sum of six 810.  
13 The distance between the requested target and the first target is therefore zero.

14 The second target environment 802 has a priority sum of one 812, so the  
15 distance between the requested target and the second target 802 is five. The third  
16 target 804 has a priority sum of two 814, so the distance between the requested  
17 target and the third target 804 is four.

18 The fourth target 806 has a priority sum of three 816, so the distance  
19 between the requested target and the fourth target 806 is three. However, in some  
20 implementations the fourth target environment 806 may be eliminated because its  
21 content will already have been localized to the intersection of Dutch and Canada,  
22 which is logically exclusive of results from the intersection of Dutch and Belgium  
23 (and 25-30 year olds). That is, since a value (Canada) for one of the requested  
24 attributes (country) in the fourth target 806 is different than a requested value  
25 (Belgium) for that attribute (country), and a value (Canada) has already been

1 intersected with a requested value (Dutch) for another attribute (language) in the  
2 desired target environment 700, the localization effected by the fourth target 806  
3 would form an empty set when intersected with a subset representing the desired  
4 target environment 700.

5 The fifth target 808 has a priority sum of one 818, so the distance between  
6 the requested target and the fifth target 808 is five. Even if the distance between a  
7 requested target and pre-existing targets (802, 804, 806, 808) is not zero (i.e., not  
8 an exact match), the distance calculations allow an exemplary content  
9 management system 800 to discern which pre-existing targets are closest to that  
10 requested, and localize resources accordingly.

11 If an exact, pre-established, target localization already exists (e.g., one with  
12 Dutch, Belgium, and "25-30 year old" values, such as the first target 700) then the  
13 comparison of priority sums will yield a zero distance, and resources of the  
14 matching target 700 can be used without further processing.

15 **Fig. 9** shows exemplary localization(s) 900 wherein multiple attributes,  
16 each having a localization priority assigned (e.g., as in exemplary attribute table  
17 400), are intersected. The areas of overlapping attributes show the relative priority  
18 sums of those combinations of attributes intersected to form an area of  
19 localization. The priority sums for an area of localization may be used to find a  
20 distance from a requested localization.

21 In the exemplary localizations 900, four attributes are intersected, or  
22 contribute, to the localizations: language 902, country 904, age group 906, and  
23 gender 908. Although four attributes are illustrated, any number could be used. It  
24 should be noted that the illustrated attributes and resulting localizations may  
25 represent multiple sets of targets (e.g., combinations of 700, 802, 804, 806, 808),

1 including pre-existing targets and/or merely hypothetical targets. In other words,  
2 attributes may used in various combinations to yield different targets and resulting  
3 localizations.

4 A requested target may be able to rely on pre-existing localizations to  
5 provide a user with a localized environment of resources. For example, if a user  
6 requests or can benefit from a localization according to the two attributes  
7 “country” 904 and “gender” 908, then a pre-existing target that yields a  
8 localization area with a priority sum representative of these two attributes (in this  
9 case six), as shown by the localized area 910, will meet a user’s needs. If the user  
10 requests or would benefit from a localization of all four shown attributes, language  
11 902, country 904, age group 906, and gender 908, then a pre-existing target that  
12 yields a localization area with a priority sum representative of these four attributes  
13 (in this case ten), as shown by the localized area 912, will meet the user’s needs.  
14 But if the resources to be localized are very numerous, e.g., worldwide, then if the  
15 localization area 912 with a priority of ten does not exist (e.g., the process of  
16 localizing has not been performed for that localization area 912) then an  
17 exemplary content management system can use pre-established localizations  
18 having the least distance for the desired localization, e.g., localization areas 914  
19 with a priority sum of seven, and localization area 910 with a priority sum of six.

20 In some implementations, an exemplary content management system can  
21 intersect two or more pre-existing localization areas (e.g., 910, 914) to achieve an  
22 approximation or an exact match of a desired localization area (e.g., 912) without  
23 having to perform a localization from scratch using each individual attribute or  
24 value in a requested target. Thus, if an example target prompts for a localization  
25 specified by values for five attributes, and a pre-existing target has already yielded

1 a localization using four of the five values, then the pre-existing localization using  
2 the four values can be intersected with the value of the fifth attribute without  
3 performing a completely new global localization using individual values already  
4 localized by the pre-existing target. A resulting localization based on values for  
5 attributes that are close but not exact to those requested or that contains attributes  
6 that are close but not exact to those requested may yield a localization that is not  
7 as specific as that which could be attained with values and attributes that match the  
8 request exactly. The additional area of localization, however (e.g., localized area  
9 916 added onto localized area 912, that latter which would represent an exact  
10 match of values and attributes of a target), may not be discernable to a user, and  
11 may be presented to a user very quickly with no additional processing, since the  
12 user's needed localization may be only a minor refinement or intersection of pre-  
13 existing localizations. Hence, the subject matter can allow quick, highly specific  
14 localizations using pre-existing resources and localizations.

15 In some implementations, pre-existing localizations of resources are known  
16 as "releases." A release can be one or more localizations of resources and/or  
17 content elements, for example, performed on a certain date. If content elements  
18 are added or subtracted from the information universe then another release of the  
19 one or more localizations may be called for to keep an exemplary content  
20 management system updated. It may be of more benefit to keep past releases  
21 available than to purge them, when creating an updated release. In some  
22 implementations, a release may also be a way to match content to characteristics  
23 of particular systems, that is, different systems may use the same data in slightly  
24 different ways, and different releases of the same localizations may take into  
25 account the differences between the systems: e.g., rather than purging one system

1 of data to start localizations from scratch, different releases of a localization may  
2 be used to afford adaptability of the content.

3 In some implementations, modules may also be used, each module being a  
4 logical way of grouping resources together. A user interface, for example, may  
5 group resources together for the purpose of facilitating the interface. Hence, in  
6 some implementations, a user may select or be presented with a content  
7 management environment in which a release is selectable, modules are selectable,  
8 and localization criteria, i.e., targets, are selectable. After an environment is  
9 selected, a user can then request data (i.e., instances of content elements) from the  
10 exemplary content management system.

11 **Fig. 10** shows an exemplary content management engine 1000. A  
12 classification engine 1002, attribute table manager 1004, values table manager  
13 1010, target criteria engine 1014, and localization engine 1016 are included in one  
14 implementation. A table of attributes having associated priorities 1006 and a  
15 prioritizer 1008 are associated with the attribute table manager 1004. A table of  
16 values having associated attributes 1012 is associated with the values table  
17 manager 1010. The exemplary content management engine 1000 may also include  
18 a set comparator 1018, set storage 1020, and a link module 1022. A content  
19 ranking module 1024 can also be included.

20 The classification engine 1002 determines and/or assigns attributes and  
21 values to information resources in an information system, for example, if the  
22 association between resources and attributes is not already pre-existing or not  
23 ascertainable by the exemplary content management engine 1000. A resource, for  
24 instance, such as a hyperlink, may exist in seven different language versions. An  
25 exemplary classification engine 1002 makes sure that the content management

1 engine 1000 can find and read attributes of resources and content elements. In  
2 some implementations, the function of a classification engine 1002 can be  
3 performed at least in part by a language, application, and/or platform employed to  
4 perform the subject matter.

5 The attribute table manager 1004 can accept user input to add and subtract  
6 attributes from the table of attributes having associated priorities 1006 and the  
7 prioritizer 1008 can likewise accept user input to assign priority weighting to  
8 attributes in the table 1006. In some implementations, the attribute table manager  
9 1004 may automatically start with a default set of attributes or a default set of  
10 priorities for certain attributes. The attribute table manager 1004 also  
11 communicates with the other components in the content management system 1000  
12 so that the values table manager 1010 can automatically adjust the table of values  
13 having associated attributes 1012 when attributes are added, subtracted, or  
14 changed in the table of attributes having associated priorities 1006 and the target  
15 criteria engine 1014 can automatically develop new and more specific sets of  
16 target criteria when attributes are added, etc.

17 The exemplary target criteria engine 1014 can create target criteria sets,  
18 e.g., via user input, consisting of one or more of the values in the values table. Of  
19 course, if a user requests target criteria that include a value not in the table of  
20 values having associated attributes 1012, the target criteria engine 1014 can  
21 approximate a target criteria set, especially as the set comparator 1018 can  
22 determine the closeness of an approximated target criteria set to a requested target  
23 criteria set using priority sums for the comparison. A target criteria set, as  
24 mentioned, designates a subset of the information resources and/or content  
25 elements in the information system based on one or more values in the set.

1       The exemplary localization engine 1016 makes information resources in a  
2 subset available to a user of the information system. If the content management  
3 engine 1000 is implemented in the context of an available query platform (e.g.,  
4 MICROSOFT® SQL SERVER 2000, ASP.NET, SQL XML extensions,  
5 MICROSOFT® ACCESS, etc.) then the platform can assist or be the exemplary  
6 localization engine 1016 (Microsoft Corporation, Redmond, Washington). The  
7 subject matter can variously employ a relational database as a backend, and use  
8 hash tables, etc., to perform the tasks of making a subset of resources and/or  
9 content elements (designated by the exemplary content management engine 1000)  
10 available to a user or set of users. In other words, some aspects of the subject  
11 matter can be implemented using at least in part, commercially available  
12 computing means.

13       The exemplary target criteria set comparator 1018 can compare priority  
14 sums of two or more target criteria sets. This allows the exemplary content  
15 management engine 1000 to rank target criteria sets with respect to closeness or  
16 distance from a requested target criteria set. An exemplary content management  
17 engine 1000 may also include a space for set storage 1020, i.e., for storing sets of  
18 localization target criteria 700.

19       In some implementations, the content management engine 1000 includes a  
20 link module 1022 to associate a preferred target criteria set to each information  
21 resource and/or to each content element included in each of the information  
22 resources. A content ranking module 1024 can compare a priority sum of each  
23 preferred target criteria set linked to content elements included in an information  
24 resource to the priority sum of the target criteria set linked to the information  
25

1 resource itself and present a user with ranked or preferred content elements  
2 according to the comparison result.

3 **Fig. 11** shows an exemplary method 1100 of managing content. In the flow  
4 diagram, the operations are summarized in individual blocks. The operations of  
5 the exemplary method 1100 may be performed in hardware and/or as machine-  
6 readable instructions (software or firmware) that can be executed by a processor or  
7 a device, such as a device that includes or comprises an exemplary content  
8 management engine 1000.

9 At block 1102, priority weight values are associated with attributes in a  
10 dynamic list of attributes associated with information resources in an information  
11 system.

12 At block 1104, instances of attribute values are associated with  
13 corresponding attributes in a dynamic list of attribute values.

14 At block 1106, subsets of the information resources are designated based on  
15 respective sets of one or more of the attribute values.

16 At block 1108, a subset that most accurately fits the target (i.e., the subset  
17 of information resources having attributes that best describe a desired user  
18 environment or need) is selected based on comparison of respective priority sums,  
19 wherein a priority sum is obtained by summing priority weight values associated  
20 with each attribute value in a set of one or more of the attribute values used to  
21 designate a subset (i.e., a target criteria set).

22 **Fig. 12** shows another exemplary method 1200 of managing content. In the  
23 flow diagram, the operations are summarized in individual blocks. The operations  
24 of the exemplary method 1200 may be performed in hardware and/or as machine-  
25 readable instructions (software or firmware) that can be executed by a processor or

1 a device, such as a device that includes an exemplary content management engine  
2 1000.

3 At block 1202, attributes for a target environment are selected relative to a  
4 user or a user need. At the end of the exemplary method 1200, the selected target  
5 environment will be “created” by presenting the user with information resources  
6 and content elements that have attributes that match the target. For example, if the  
7 user is a French youth, then the target environment might consist of “France” and  
8 “French” and “age 13 to 19.” Information resources with matching attributes  
9 would then be presented to the user, e.g., content elements in French, etc.

10 At block 1204, content is requested from the information system.

11 At block 1206, a list of possible or known target criteria sets is produced  
12 based on the selected target environment.

13 At block 1208, each target criteria set is assigned a priority sum according  
14 to attributes represented by values in each set.

15 At block 1210, each set in the list of target criteria sets is ranked according  
16 to the priority sums.

17 At block 1212, a list of information resources is compiled based on the  
18 selected target environment and the ranked list of target criteria sets.

19 At block 1214, a list of content elements (instances) is compiled based on  
20 instances of content that apply to the list of information resources, the list of target  
21 criteria, and the target environment selected.

22 At block 1216, each information resource and/or each content element is  
23 mapped or has previously been mapped to a preferred set of target criteria having a  
24 priority sum.

1       At block 1218, the difference (distance) is determined between the priority  
2 sum of the set of target criteria that describes the target environment selected by  
3 the user and the priority sum of the preferred set of target criteria mapped to each  
4 information resource and/or content element.

5       At block 1220, the information resource(s) and/or the content element(s)  
6 associated with the least distance from the target environment selected by the user  
7 are ranked first. Within an information resource, content elements may be mapped  
8 to different sets of target criteria. The difference between a priority sum of a set of  
9 target criteria mapped to a content element and the priority sum of a set of target  
10 criteria mapped to the information resource possessing the content element may be  
11 calculated to establish a rank between content elements in the information  
12 resource.

13       A user may want to start out with content that is most specific to the user's  
14 environment. An exemplary content management system can automatically locate  
15 the most specific information that exists in the exemplary system for each item of  
16 content the user is localizing, and return it to the user.

17       But a user can also prefer a more general target environment than the  
18 system would otherwise automatically choose. For example, a Japanese user may  
19 want the Japanese view of an information resource to always include the English  
20 version of the resource. A user can have an exemplary system obtain a content  
21 string in Japanese, find the string in English, and try to translate it and localize it.

22       This user preference for a more general target environment than  
23 automatically provided by an exemplary system by default can rise to the level of  
24 an override. For example, regardless of any other circumstance, a user may select  
25 to see resources with a "Belgium" value for a country attribute.

1       **Fig. 13** shows an exemplary computer 1300 providing a computing  
2 environment in which aspects of the subject matter could be practiced. The  
3 components of exemplary computer 1300 may include, but are not limited to, a  
4 processing unit 1320, a system memory 1330, and a system bus 1321 that couples  
5 various system components including the system memory 1330 to the processing  
6 unit 1320. The system bus 1321 may be any of several types of bus structures  
7 including a memory bus or memory controller, a peripheral bus, and a local bus  
8 using any of a variety of bus architectures. By way of example, and not limitation,  
9 such architectures include Industry Standard Architecture (ISA) bus, Micro  
10 Channel Architecture (MCA) bus, Enhanced ISA (EISAA) bus, Video Electronics  
11 Standards Association (VESA) local bus, and Peripheral Component Interconnect  
12 (PCI) bus also known as the Mezzanine bus.

13       Exemplary computer 1300 typically includes a variety of computer-  
14 readable media. Computer-readable media can be any available media that can be  
15 accessed by exemplary computer 1300 and includes both volatile and nonvolatile  
16 media, removable and non-removable media. By way of example, and not  
17 limitation, computer-readable media may comprise computer storage media and  
18 communication media. Computer storage media include volatile and nonvolatile,  
19 removable and non-removable media implemented in any method or technology  
20 for storage of information such as computer-readable instructions, data structures,  
21 program modules, or other data. Computer storage media includes, but is not  
22 limited to, RAM, ROM, EEPROM, flash memory or other memory technology,  
23 CD-ROM, digital versatile disks (DVD) or other optical disk storage, magnetic  
24 cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices,  
25 or any other medium which can be used to store the desired information and which

1 can be accessed by exemplary computer 1300. Communication media typically  
2 embodies computer-readable instructions, data structures, program modules or  
3 other data in a modulated data signal such as a carrier wave or other transport  
4 mechanism and includes any information delivery media. The term "modulated  
5 data signal" means a signal that has one or more of its characteristics set or  
6 changed in such a manner as to encode information in the signal. By way of  
7 example, and not limitation, communication media includes wired media such as a  
8 wired network or direct-wired connection and wireless media such as acoustic,  
9 RF, infrared and other wireless media. Combinations of any of the above should  
10 also be included within the scope of computer readable media.

11 The system memory 1330 includes computer storage media in the form of  
12 volatile and/or nonvolatile memory such as read only memory (ROM) 1331 and  
13 random access memory (RAM) 1332. A basic input/output system 1333 (BIOS),  
14 containing the basic routines that help to transfer information between elements  
15 within exemplary computer 1300, such as during start-up, is typically stored in  
16 ROM 1331. RAM 1332 typically contains data and/or program modules that are  
17 immediately accessible to and/or presently being operated on by processing unit  
18 1320. By way of example, and not limitation, Fig. 13 illustrates operating system  
19 1334, the exemplary content management engine 1000, application programs  
20 1335, other program modules 1336, and program data 1337. Although the  
21 exemplary content management engine 1000 is depicted as software in random  
22 access memory 1332, other implementations of an exemplary content management  
23 engine 1000 can be hardware or combinations of software and hardware.

24 The exemplary computer 1300 may also include other removable/non-  
25 removable, volatile/nonvolatile computer storage media. By way of example only,

1 Fig. 13 illustrates a hard disk drive 1341 that reads from or writes to non-  
2 removable, nonvolatile magnetic media, a magnetic disk drive 1351 that reads  
3 from or writes to a removable, nonvolatile magnetic disk 1352, and an optical disk  
4 drive 1355 that reads from or writes to a removable, nonvolatile optical disk 1356  
5 such as a CD ROM or other optical media. Other removable/non-removable,  
6 volatile/nonvolatile computer storage media that can be used in the exemplary  
7 operating environment include, but are not limited to, magnetic tape cassettes,  
8 flash memory cards, digital versatile disks, digital video tape, solid state RAM,  
9 solid state ROM, and the like. The hard disk drive 1341 is typically connected to  
10 the system bus 1321 through a non-removable memory interface such as interface  
11 1340, and magnetic disk drive 1351 and optical disk drive 1355 are typically  
12 connected to the system bus 1321 by a removable memory interface such as  
13 interface 1350.

14 The drives and their associated computer storage media discussed above  
15 and illustrated in Fig. 13 provide storage of computer-readable instructions, data  
16 structures, program modules, and other data for exemplary computer 1300. In Fig.  
17 13, for example, hard disk drive 1341 is illustrated as storing operating system  
18 1344, application programs 1345, other program modules 1346, and program data  
19 1347. Note that these components can either be the same as or different from  
20 operating system 1334, application programs 1335, other program modules 1336,  
21 and program data 1337. Operating system 1344, application programs 1345, other  
22 program modules 1346, and program data 1347 are given different numbers here  
23 to illustrate that, at a minimum, they are different copies. A user may enter  
24 commands and information into the exemplary computer 1300 through input  
25 devices such as a keyboard 1362 and pointing device 1361, commonly referred to

1 as a mouse, trackball, or touch pad. Other input devices (not shown) may include  
2 a microphone, joystick, game pad, satellite dish, scanner, or the like. These and  
3 other input devices are often connected to the processing unit 1320 through a user  
4 input interface 1360 that is coupled to the system bus, but may be connected by  
5 other interface and bus structures, such as a parallel port, game port, or a universal  
6 serial bus (USB). A monitor 1391 or other type of display device is also  
7 connected to the system bus 1321 via an interface, such as a video interface 1390.  
8 In addition to the monitor 1391, computers may also include other peripheral  
9 output devices such as speakers 1397 and printer 1396, which may be connected  
10 through an output peripheral interface 1395.

11 The exemplary computer 1300 may operate in a networked environment  
12 using logical connections to one or more remote computers, such as a remote  
13 computer 1380. The remote computer 1380 may be a personal computer, a server,  
14 a router, a network PC, a peer device or other common network node, and  
15 typically includes many or all of the elements described above relative to  
16 exemplary computer 1300, although only a memory storage device 1381 has been  
17 illustrated in Fig. 13. The logical connections depicted in Fig. 13 include a local  
18 area network (LAN) 1371 and a wide area network (WAN) 1373, but may also  
19 include other networks. Such networking environments are commonplace in  
20 offices, enterprise-wide computer networks, intranets, and the Internet.

21 When used in a LAN networking environment, the exemplary computer  
22 1300 is connected to the LAN 1371 through a network interface or adapter 1370.  
23 When used in a WAN networking environment, the exemplary computer 1300  
24 typically includes a modem 1372 or other means for establishing communications  
25 over the WAN 1373, such as the Internet. The modem 1372, which may be

1 internal or external, may be connected to the system bus 1321 via the user input  
2 interface 1360, or other appropriate mechanism. In a networked environment,  
3 program modules depicted relative to the exemplary computer 1300, or portions  
4 thereof, may be stored in the remote memory storage device. By way of example,  
5 and not limitation, Fig. 13 illustrates remote application programs 1385 as residing  
6 on memory device 1381. It will be appreciated that the network connections  
7 shown are exemplary and other means of establishing a communications link  
8 between the computers may be used.

## 10 CONCLUSION

11 The foregoing describes an exemplary resource classification and  
12 prioritization system and related methods. The subject matter described above can  
13 be implemented in hardware, in software, or in both hardware and software. In  
14 certain implementations, the exemplary resource classification and prioritization  
15 system and related methods may be described in the general context of computer-  
16 executable instructions, such as program modules, being executed by a computer.  
17 Generally, program modules include routines, programs, objects, components, data  
18 structures, etc. that perform particular tasks or implement particular abstract data  
19 types. The subject matter can also be practiced in distributed communications  
20 environments where tasks are performed over wireless communication by remote  
21 processing devices that are linked through a communications network. In a  
22 wireless network, program modules may be located in both local and remote  
23 communications device storage media including memory storage devices.
